1 PREMESSA

Nel presente documento vengono illustrati i risultati del dimensionamento delle nuove pavimentazioni e degli interventi di risanamento delle pavimentazioni esistenti previste nell'ambito del progetto.

Per quanto attiene agli interventi di risanamento delle attuali corsie di marcia dinamica/emergenza e normale dell'autostrada A14 (future corsie di marcia lenta e marcia veloce), questi sono stati previsti laddove i risultati della verifiche prestazionali delle pavimentazioni (definite a seguito di una campagna di carotaggi e di indagini mediante prove ad alto rendimento GPR e FWD) sono risultati inadeguati secondo quanto esposto nella relazione "Analisi delle caratteristiche strutturali delle pavimentazioni esistenti" allegata al presente progetto.

2 DESCRIZIONE DELLE SOVRASTRUTTURE DI PROGETTO

2.1 PAVIMENTAZIONI SU NUOVO SEDIME

2.1.1 Autostrada e tangenziale

Il progetto delle pavimentazioni per l'ampliamento della piattaforma della tangenziale (in seguito alla completa demolizione della sovrastruttura dell'attuale emergenza) e per la realizzazione della nuova piattaforma sia in autostrada che in tangenziale nel caso di varianti planimetriche e/o altimetriche, ha previsto l'impiego di un pacchetto di spessore complessivo pari a 84 cm con una sovrastruttura così composta:

- Usura drenante in conglomerato bituminoso (CB) con bitumi modificati tipo Hard di 4 cm;
- Binder in CB con bitumi modificati tipo Hard di 5 cm;
- Base in CB con bitumi modificati tipo Hard di 25 cm;
- Fondazione legata in misto cementato di 30 cm;
- Fondazione non legata in misto granulare di 20 cm.

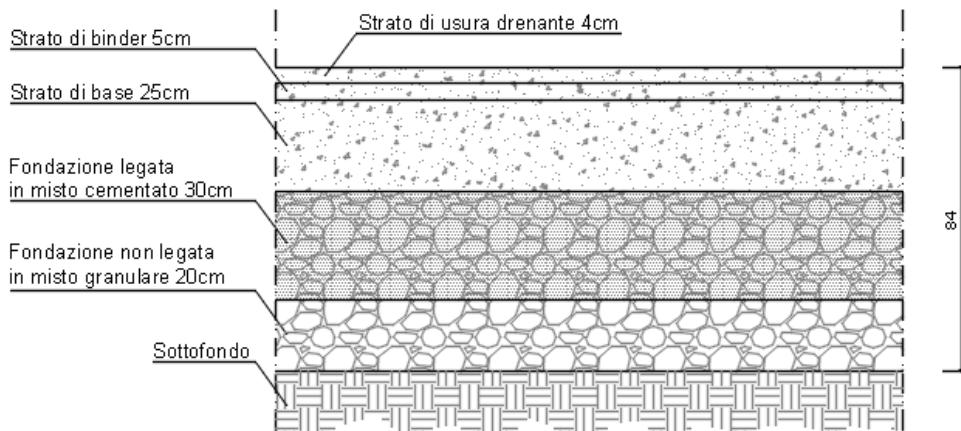

Figura 2-1. Composizione della sovrastruttura di progetto_Nuovo sedime A14 e tangenziale

Per l'adeguamento delle rampe degli svincoli esistenti è previsto l'impiego della suddetta sovrastruttura.

Lo strato di usura drenante verrà realizzato in un'unica fase sull'intera piattaforma.

Lungo le corsie specializzate di immissione/diversione è previsto uno strato di usura di tipo drenante in analogia con quanto previsto sull'asse principale (al fine di garantire la continuità idraulica sull'intera piattaforma per lo smaltimento delle acque).

Per i tratti su impalcato è prevista la stesa dei soli strati di binder e usura drenante/chiusa con l'interposizione tra la soletta e la pavimentazione di uno strato di impermeabilizzazione di spessore pari a 1 cm.

2.1.2 Nuovo svincolo di Lazzaretto

Per le rampe del nuovo svincolo di Lazzaretto è previsto l'impiego di un pacchetto di spessore complessivo pari a 59 cm con una sovrastruttura così composta:

- Usura in conglomerato bituminoso (CB) di tipo chiuso con bitumi modificati tipo Hard di 4 cm;
- Binder in CB con bitumi modificati tipo Hard di 5 cm;
- Base in CB con bitumi modificati tipo Hard di 10 cm;
- Fondazione legata in misto cementato di 20 cm;

- Fondazione non legata in misto granulare di 20 cm.

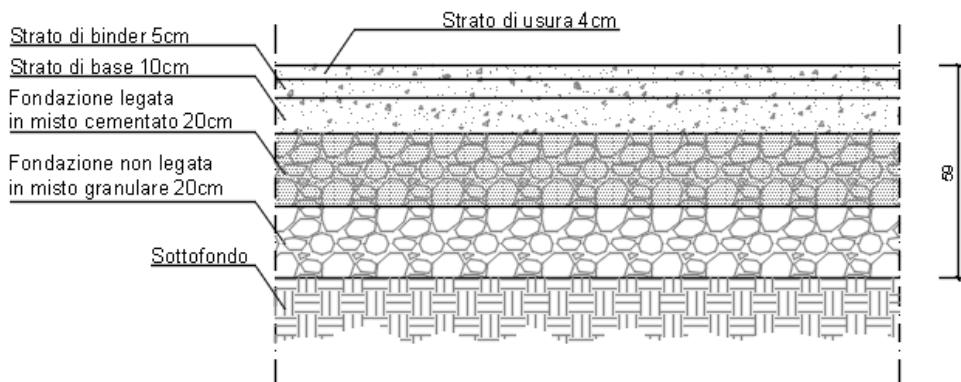

Figura 2-2. Composizione della sovrastruttura di progetto_Rampe nuovo svincolo Lazzaretto

In corrispondenza delle rampe di svincolo lo strato di usura dovrà essere realizzato in conglomerato bituminoso di tipo chiuso con bitumi modificati di tipo hard.

Lungo le corsie specializzate di immissione/diversione è previsto uno strato di usura di tipo drenante in analogia con quanto previsto sull'asse principale (al fine di garantire la continuità idraulica sull'intera piattaforma per lo smaltimento delle acque).

2.2 RISANAMENTO DELLE PAVIMENTAZIONI ESISTENTI

Il progetto prevede una serie di lavorazioni volte al risanamento sia superficiale che profondo della pavimentazione che vengono qui di seguito descritte.

2.2.1 Intervento di prima fase

La lavorazione che viene effettuata prima della fase di cantiere sia sulla piattaforma dell'autostrada che della tangenziale è la rimozione degli strati di binder e usura drenante attualmente in opera attraverso il seguente intervento:

- Fresatura conglomerati bituminosi per uno spessore di 8cm;
- Stesa strato di binder in CB con bitumi modificati tipo Hard di 4 cm.

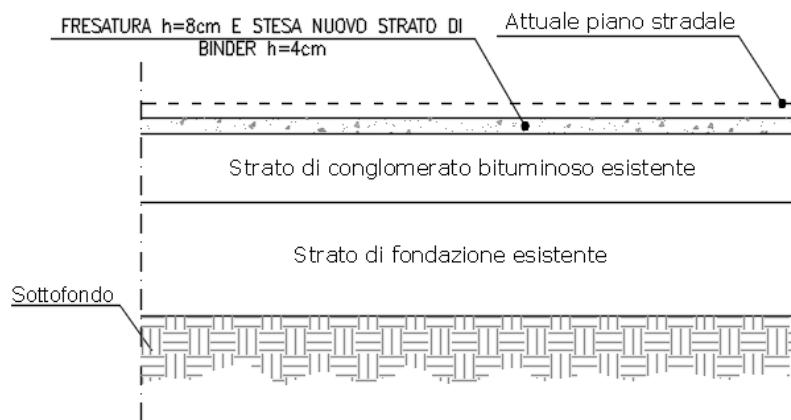

Figura 2-3. Intervento prima fase

L'intervento sopra descritto è stato definito allo scopo di rimuovere lo strato di usura drenante esistente al fine di non mantenere in opera strati intermedi ad alto contenuto di vuoti all'interno dei quali, durante l'esercizio dell'infrastruttura, potrebbe penetrare acqua, con conseguente accelerazione dei fenomeni di degrado e, nel

caso di gelo, formazione di rigonfiamenti all'interno dello strato e successiva propagazione dei dissesti in superficie. Il nuovo strato di binder fungerà da supporto per la realizzazione della segnaletica di cantiere nonché per gli interventi successivi previsti in progetto (in particolare imbottitura e/o stesa del nuovo strato di usura).

2.2.2 Risanamenti superficiali

Con riferimento ai risanamenti superficiali, codice 3, le lavorazioni che vengono effettuate dopo la fase di cantiere sono le seguenti:

- A. Realizzazione dello strato di usura drenante in conglomerato bituminoso in assenza di imbottitura attraverso il seguente intervento, denominato TIPO 3A:
 - 1. Realizzazione dello strato di usura drenante in conglomerato bituminoso ($h=4\text{cm}$).
- B. Realizzazione dello strato di usura drenante in conglomerato bituminoso in presenza di imbottitura attraverso il seguente intervento, denominato TIPO 3B:
 - 1. Imbottitura in conglomerato bituminoso;
 - 2. Realizzazione dello strato di collegamento (binder) in conglomerato bituminoso ($h=5\text{cm}$);
 - 3. Realizzazione dello strato di usura drenante in conglomerato bituminoso ($h=4\text{cm}$).

2.2.3 Risanamenti profondi

Per quanto riguarda i risanamenti profondi, codice 2, delle attuali corsie autostradali di marcia dinamica/emergenza (futura marcia lenta) e marcia normale (futura marcia veloce), sono previste quattro condizioni di intervento che hanno portato a definire 4 pacchetti di pavimentazione qui di seguito descritti.

Pacchetto di risanamento TIPO 2A

In corrispondenza dell'attuale corsia autostradale di marcia dinamica/emergenza (futura corsia di marcia lenta) in carreggiata sud, l'analisi dimensionale ha previsto l'impiego di un pacchetto di spessore complessivo pari a 64 cm con una sovrastruttura così composta:

- Usura drenante in conglomerato bituminoso (CB) con bitumi modificati tipo Hard di 4 cm;
- Binder in CB con bitumi modificati tipo Hard di 5 cm;
- Base in CB con bitumi modificati tipo Hard di 25 cm;
- Fondazione legata in misto cementato di 30 cm.

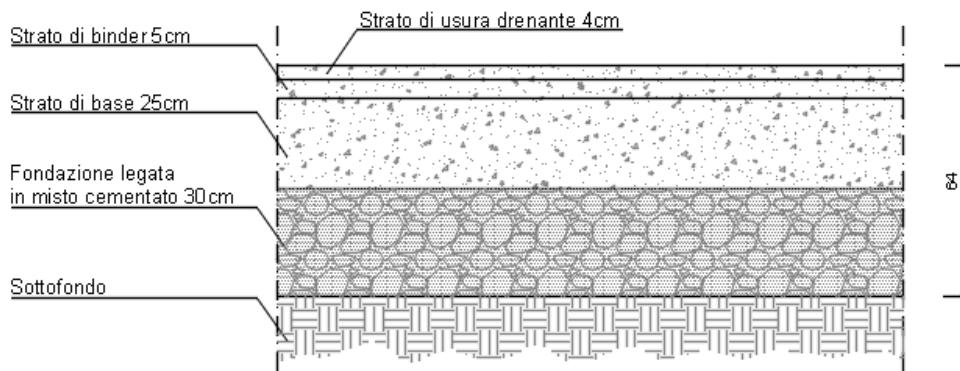

Figura 2-4. Pacchetto di risanamento TIPO 2A

L'intervento prevede la fresatura degli strati in conglomerato bituminoso e la demolizione della porzione restante di cassonetto necessaria a raggiungere la quota di posa della nuova sovrastruttura.

Pacchetto di risanamento TIPO 2B

In corrispondenza dell'attuale corsia autostradale di marcia dinamica/emergenza (futura corsia di marcia lenta) in carreggiata nord, l'analisi dimensionale ha previsto il rifacimento dei soli conglomerati bituminosi con una stratigrafia così composta:

- Usura drenante in conglomerato bituminoso (CB) con bitumi modificati tipo Hard di 4 cm;
- Binder in CB con bitumi modificati tipo Hard di 5 cm;
- Base in CB con bitumi modificati tipo Hard di 20 cm.

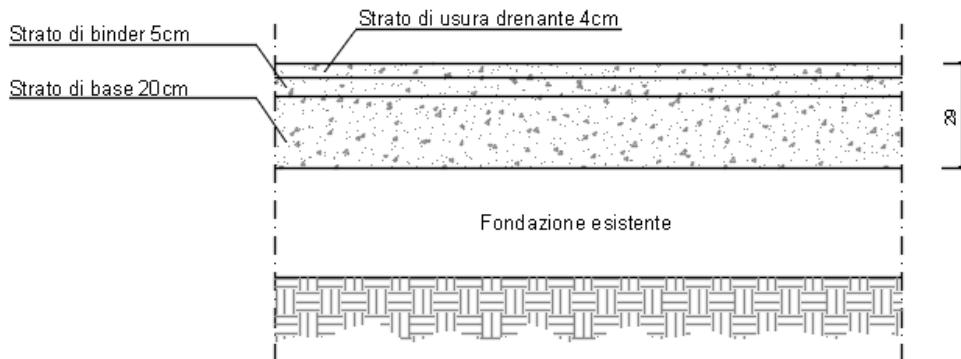

Figura 2-5. Pacchetto di risanamento TIPO 2B

L'intervento prevede la fresatura degli strati in conglomerato bituminoso fino a raggiungere la quota di posa dei nuovi strati.

Pacchetto di risanamento TIPO 2C

In corrispondenza dell'attuale corsia autostradale di marcia dinamica/emergenza (futura corsia di marcia lenta) in carreggiata nord, l'analisi dimensionale ha previsto il rifacimento dei soli conglomerati bituminosi con una stratigrafia così composta:

- Usura drenante in conglomerato bituminoso (CB) con bitumi modificati tipo Hard di 4 cm;
- Binder in CB con bitumi modificati tipo Hard di 5 cm;
- Base in CB con bitumi modificati tipo Hard di 25 cm.

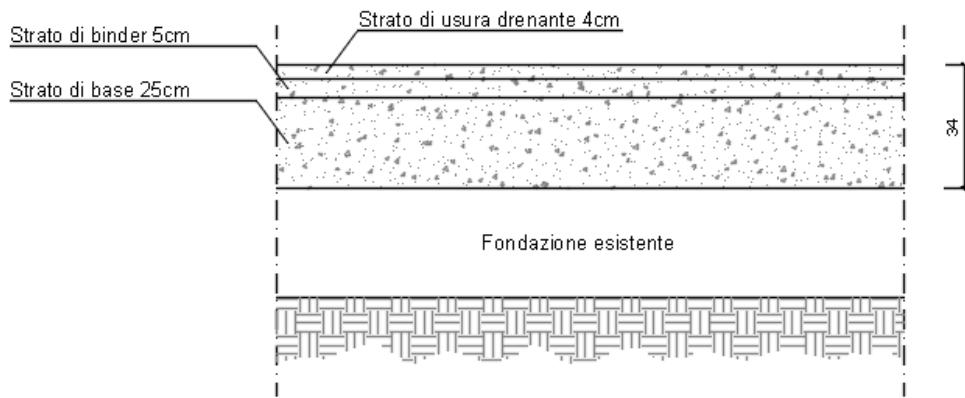

Figura 2-6. Pacchetto di risanamento TIPO 2C

L'intervento prevede la fresatura degli strati in conglomerato bituminoso fino a raggiungere la quota di posa dei nuovi strati.

Pacchetto di risanamento TIPO 2D

In corrispondenza dell'attuale corsia autostradale di marcia normale (futura marcia veloce) in entrambe le carreggiate, l'analisi dimensionale ha previsto l'impiego di un pacchetto di spessore complessivo pari a 59 cm con una sovrastruttura così composta:

- Usura drenante in conglomerato bituminoso (CB) con bitumi modificati tipo Hard di 4 cm;
- Binder in CB con bitumi modificati tipo Hard di 5 cm;
- Base in CB con bitumi modificati tipo Hard di 20 cm;
- Fondazione legata in misto cementato di 30 cm.

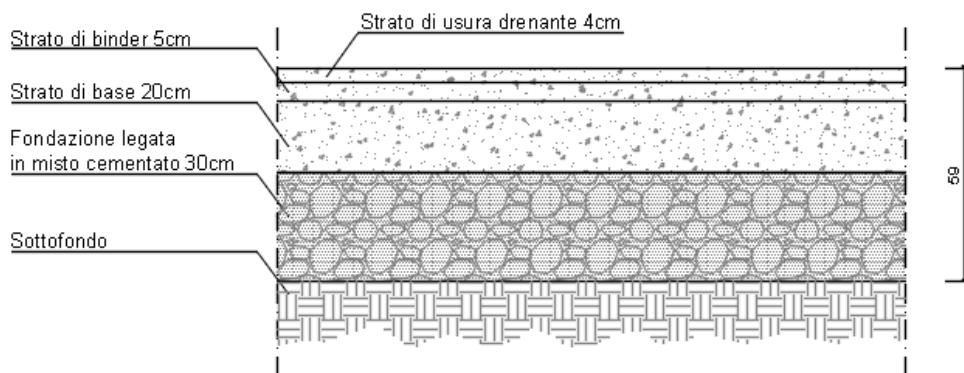

Figura 2-7. Pacchetto di risanamento TIPO 2D

L'intervento prevede la fresatura degli strati in conglomerato bituminoso e la demolizione della porzione restante di cassonetto necessaria a raggiungere la quota di posa della nuova sovrastruttura.

In Tabella 2-1 è riportato l'elenco delle tratte a cui corrispondono le suddette tipologie di risanamento.

2.3 RIQUALIFICA DELLO SPARTITRAFFICO A14 - TANGENZIALE

Il progetto prevede l'impiego della seguente sovrastruttura:

- Usura drenante in conglomerato bituminoso (CB) con bitumi modificati tipo Hard di 4 cm;
- Binder in CB con bitumi modificati tipo Hard di 5 cm;
- Base in CB con bitumi modificati tipo Hard di 25 cm;
- Fondazione legata in misto cementato di 30 cm.

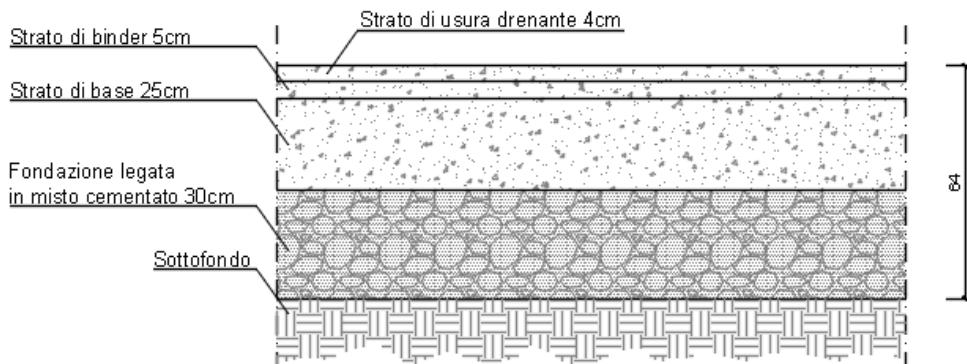

Figura 2-8. Composizione della sovrastruttura di progetto_Riqualifica spartitraffico A14 - Tangenziale

2.4 DATI DI INPUT

Per la valutazione della vita utile della sovrastruttura di progetto si sono resi necessari i seguenti dati di input:

1. caratteristiche di portanza dei terreni di sottofondo esistenti e di nuova realizzazione;
2. caratteristiche tenso-deformative e di resistenza dei materiali impiegati per la realizzazione delle nuove sovrastrutture;
3. temperature caratteristiche dell'aria nella zona in cui è ubicato l'intervento;
4. flussi di traffico commerciale previsti nell'arco del periodo di progetto nel tratto di intervento.

2.4.1 Caratteristiche di portanza del terreno di sottofondo

Le caratteristiche di portanza del terreno di sottofondo delle nuove pavimentazioni su nuovo sedime sono state desunte dalle prescrizioni contenute nel Capitolato Tecnico d'Appalto [1]. A tale proposito si riporta quanto segue:

“Salvo diverse e più restrittive prescrizioni motivate in sede di progettazione dalla necessità di garantire la stabilità del rilevato, il modulo di deformazione M_d al primo ciclo di carico su piastra (diametro 30 cm) dovrà risultare non inferiore a 60 MPa nell'intervallo compreso tra 1,5÷2,5 daN/cm² sul piano di posa della fondazione della pavimentazione autostradale in rilevato, in trincea e nel riempimento dell'arco rovescio in galleria; ...”.

Per determinare il valore di progetto del modulo elastico si è fatto quindi riferimento alle seguenti correlazioni, proposta da Ferrari/Giannini [2] e riportata anche negli allegati al Catalogo delle Pavimentazioni Stradali [3]:

$$E_{din} (\text{MPa}) = 1.9 \div 2.1 M_d$$

Nei calcoli si è quindi assunto come valore di progetto un valore del modulo dinamico pari a 120 MPa.

Le caratteristiche di portanza del terreno di sottofondo, nei tratti in cui è previsto un risanamento di tipo profondo, sono state desunte dai risultati della campagna di prove ad alto rendimento (carotaggi, prove GPR e prove FWD); in particolare si è assunto come valore di progetto il modulo minimo rilevato nelle tratte che necessitano di tale intervento.

Il corrispondente rapporto di Poisson è stato assunto pari a 0.40.

2.4.2 Misto granulare non legato

Le caratteristiche meccaniche del misto granulare sono state stimate facendo riferimento alla espressione di Heukelom e Klomp che, in virtù del comportamento non lineare dei materiali non legati, fa discendere il valore del **modulo elastico** del misto granulare dal suo spessore e dalle caratteristiche del terreno di sottofondo su cui è appoggiato:

$$E_2 = 0.206 \cdot h^{0.45} \cdot E_1$$

dove:

E_2 = modulo elastico del misto granulare

E_1 = modulo elastico del sottofondo

h = spessore in mm dello strato di misto granulare

Per strati di spessore pari a 20 cm, poggianti su un sottofondo di modulo pari a 120 MPa, si è considerato un valore di calcolo pari a 268 MPa.

Il rapporto di Poisson è stato assunto pari a 0.40.

2.4.3 Misto cementato

Nelle soluzioni progettuali individuate è prevista la realizzazione di una sovrastruttura comprendente, al di sotto degli strati legati a bitume, uno strato in misto cementato di spessore pari a 20 cm.

Le caratteristiche meccaniche del misto cementato da assumere nel progetto sono state desunte dalle Norme Tecniche. Per tali materiali è previsto un nomogramma di controllo che oltre i 90 giorni di maturazione stabilisce un intervallo di accettazione del modulo dinamico rilevato mediante FWD compreso tra 4000 e 12000 MPa. A questo proposito le stesse Norme Tecniche stabiliscono quanto segue:

"Il riferimento prestazionale sarà costituito dal modulo elastico reale derivato mediante retrocalcolo con i valori rilevati in opera (anche a strato ricoperto) con il F.W.D. in un periodo compreso tra 7 e 90 giorni dalla stessa. La media dei valori di modulo sui tronchi omogenei dovrà essere quella compresa nell'area A del diagramma che segue".

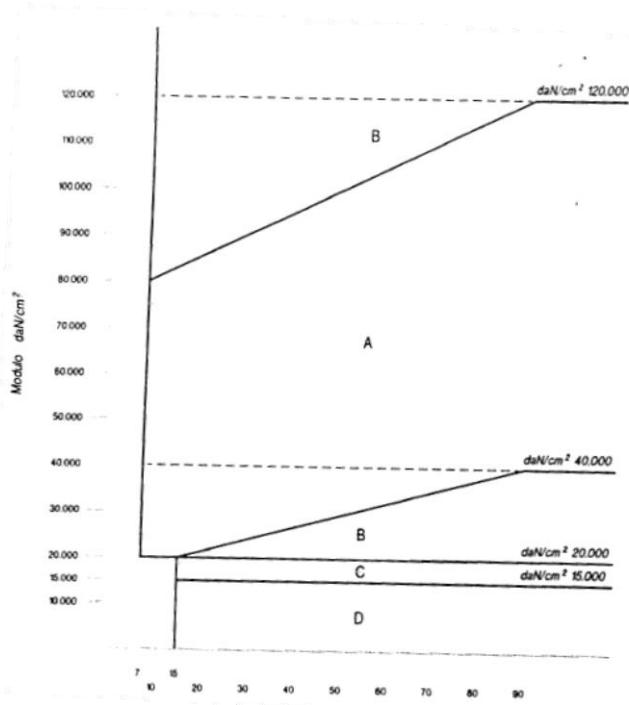

Figura 9 - Diagramma di controllo della media dei moduli dinamici relativi al misto cementato

Nei calcoli si è pertanto assunto un valore prudentiale del modulo pari a 3000 MPa, sia per garantire buoni margini di sicurezza per la variabilità di prestazione che il materiale può manifestare durante la produzione ed all'atto della messa in opera, sia per non trascurare i fenomeni di fessurazione che inevitabilmente lo interessano nel corso della sua vita utile.

Il rapporto di Poisson è stato assunto pari a 0.25.

2.4.4 Conglomerati bituminosi

Le caratteristiche meccaniche dei conglomerati bituminosi, espresse in termini di modulo elastico e di coefficiente di Poisson, sono state valutate, facendo riferimento agli studi di Francken [4], sulla base delle grandezze volumetriche che caratterizzano il conglomerato (percentuale dei vuoti e volume percentuale degli aggregati) e delle proprietà reologiche dei leganti (modulo complesso ridotto).

In particolare il modulo complesso ridotto del bitume è stato determinato tramite correlazione con il modulo di rigidezza S_b .

Le caratteristiche volumetriche delle miscele costituenti i singoli strati sono state estratte dalle Norme Tecniche. Queste prevedono:

- per miscele drenanti-fonoassorbenti una percentuale di bitume compresa tra il 5 ed il 6% ed una percentuale dei vuoti corrispondente a 50 rotazioni della pressa giratoria maggiore o uguale al 20%;
- per miscele di usura una percentuale di bitume compresa tra il 5 ed il 6.5% ed una percentuale dei vuoti corrispondente a 150 rotazioni della pressa giratoria compresa tra il 3 ed il 5%;
- per miscele di collegamento una percentuale di bitume (Hard) compresa tra il 4.5 ed il 6% ed una percentuale dei vuoti corrispondente a 120 rotazioni della pressa giratoria compresa tra il 3 ed il 5%;
- per miscele di base una percentuale di bitume (Hard) compresa tra il 4 ed il 5.5% ed una percentuale dei vuoti corrispondente a 120 rotazioni della pressa giratoria compresa tra il 3 ed il 5%.

Nei calcoli si sono pertanto utilizzati i valori mediani degli intervalli di accettazione della percentuale di bitume, mentre per le percentuali dei vuoti si sono prudentialmente assunti valori coincidenti con gli estremi superiori degli intervalli su citati.

In mancanza di sperimentazione diretta sui leganti da utilizzare effettivamente nella realizzazione della sovrastruttura, per la stima delle proprietà reologiche del legante, si è fatto riferimento ai risultati di uno studio *Round Robin* condotto nell'ambito del RILEM e coordinato dal Belgian Road Research Centre [5]. I valori del modulo di rigidezza S_b erano disponibili ad una frequenza di sollecitazione di 10 Hz ed a temperature T pari a 10, 22 e 40°C. Per estrapolare tali risultati al di fuori dell'intervallo di indagine si è pertanto operata una modellazione della relazione S_b -T mediante funzione di tipo esponenziale:

$$S_b = 627 \cdot 45 \cdot e^{-0.1387 \cdot T (\text{ }^{\circ}\text{C})}$$

La funzione così ottenuta è stata utilizzata per la valutazione del modulo normale ridotto B^* (mediante quindi il calcolo del modulo di rigidezza S_b del legante per ciascuna temperatura media mensile caratterizzante il singolo strato di pavimentazione) da inserire nelle relazioni di Francken per il calcolo del modulo normale complesso E^* . I risultati di queste elaborazioni riguardanti le miscele bituminose sono contenute nell'**Allegato C**.

Per tutte le miscele bituminose si è assunto un valore del rapporto di Poisson pari a 0.35.

2.4.5 Temperatura della pavimentazione

In mancanza di specifiche informazioni, si è fatto riferimento ai dati climatici rilevati negli ultimi 30 anni dalla stazione meteoclimatica di Bologna. Tali dati climatici sono stati utilizzati (**Allegato A**) per la valutazione delle temperature caratteristiche degli strati in conglomerato bituminoso utilizzando la formulazione di Marchionna:

$$T_{PAV} = (1.467 + 0.043 \cdot z) + (1.362 - 0.005 \cdot z) \cdot T_a$$

dove:

- $i = i$ -esimo strato;
- $z =$ quota media dello spessore dell' i -esimo strato rispetto alla sommità della pavimentazione;
- $T_a =$ temperatura media mensile dell'aria, espressa in °C.

2.4.6 Flussi di traffico e numero di ripetizioni di carico di progetto

La determinazione del numero di carichi che dovrà sopportare la struttura della pavimentazione è stata effettuata tenendo conto dei soli veicoli commerciali (commerciali leggeri + commerciali pesanti) in quanto questi sono gli unici che influenzano il comportamento strutturale.

I dati di traffico sono stati elaborati a partire dai seguenti scenari contenuti nell'elaborato Studio di Traffico allegato al progetto:

- Scenario Progettuale 2030;
- Scenario Progettuale 2040.

I flussi di traffico commerciale utilizzati per la verifica delle pavimentazioni sono riportati nell'**Allegato B**.

Per quanto riguarda la verifica della sovrastruttura per pavimentazioni su nuovo sedime questa è stata condotta facendo riferimento al tratto elementare maggiormente critico, tra autostrada e tangenziale, dal punto di vista dei carichi di traffico commerciale a cui sarà soggetta la pavimentazione.

Per gli interventi di risanamento sulle attuali corsie di marcia dinamica e marcia normale dell'autostrada si è fatto riferimento al tratto elementare autostradale più carico dal punto di vista del traffico per ciascuna tipologia di risanamento.

Per l'infrastruttura è stato ipotizzato un periodo di progetto pari a 20 anni.

Per quanto riguarda la verifica della sovrastruttura per pavimentazioni su nuovo sedime in autostrada e tangenziale e per il risanamento 2D, presenti su entrambe le carreggiate, a partire dal dato di TGMA bidirezionale si è ipotizzata una suddivisione omogenea (50/50) tra le due direzioni di traffico.

Per quanto riguarda la verifica della sovrastruttura per i risanamenti 2A – 2B – 2C, presenti su una sola carreggiata, è stato utilizzato il dato di traffico presente sulla carreggiata in cui ricadono.

E' stata inoltre considerata una percentuale del traffico commerciale transitante pari al 70% nel caso di nuove pavimentazioni in autostrada e tangenziale, in quanto rappresenta la situazione più gravosa tra quelle presenti, mentre per quanto riguarda i risanamenti profondi in autostrada è stata considerata una percentuale del traffico commerciale transitante sulle future corsie di marcia lenta (attuale corsia dinamica/emergenza) e veloce dell'autostrada (attuale corsia di marcia normale) rispettivamente pari al 70% (interventi 2A – 2B – 2C) e 30% (intervento 2D).

Per le nuove rampe dello svincolo Lazzaretto la verifica è stata condotta facendo riferimento al volume di traffico commerciale che transiterà sulla rampa più carica ovvero l'uscita in carreggiata sud in tangenziale.

Il traffico commerciale di progetto transitante è stato successivamente determinato attraverso la conversione in passaggi di assi equivalenti singoli da 80 kN, secondo la metodologia proposta dall'Asphalt Institute [6], che a sua volta fa riferimento ai fattori di conversione proposti dall'AASTHO Guide [7].

Con riferimento agli spettri di traffico riportati nel Catalogo Italiano delle Pavimentazioni [3], si è assunto un coefficiente di equivalenza tra un generico veicolo commerciale ed un asse da 80 kN pari a 2.5.

In funzione di quanto riportato nel Catalogo Italiano delle Pavimentazioni [3], considerato che lo studio trasportistico evidenzia una mix di traffico commerciale con una componente prevalente di veicoli con più di 2 assi (classi di pedaggio 3-4-5), e quindi difforme da quella di riferimento per la tipologia di infrastruttura in oggetto, si è proceduto alla ridefinizione dello spettro di traffico; il coefficiente di equivalenza tra un generico veicolo commerciale ed un asse da 80 kN è stato quindi assunto pari a 3.0 (anziché lo standard pari a 2.5) ottenuto ridefinendo lo spettro relativo ad un'autostrada extraurbana ed in particolare prevedendo una componente maggiore di traffico relativa ai veicoli con classe di pedaggio 3-4-5 (3, 4, 5 o più assi) in funzione di quanto desunto dallo studio trasportistico. Per quanto riguarda le nuove rampe dello svincolo di Lazzaretto è stato assunto il coefficiente standard pari a 2.5.

Ai fini del calcolo strutturale, il numero di ripetizioni di carico di progetto è stato espresso in termini di assi equivalenti/mese.

I flussi di traffico sono stati distribuiti omogeneamente nei 12 periodi mensili e così associati alle corrispondenti caratteristiche tenso-deformative degli strati legati a bitume.

2.5 CRITERI DI VERIFICA

I criteri di verifica utilizzati nel calcolo delle pavimentazioni sono quelli proposti dall'Asphalt Institute [6]. Questi trattano separatamente la fessurazione a fatica dei conglomerati, messa in relazione con la massima deformazione di trazione degli strati legati a bitume, e la formazione di ormaie, messa in relazione con la massima deformazione di compressione che si realizza sulla sommità del sottofondo. Il raggiungimento delle condizioni ultime (raggiungimento del Danno unitario) corrisponde, secondo quanto indicato negli studi dell'Asphalt Institute, ad una fessurazione sul 20% della superficie della pavimentazione ed alla formazione di ormaie aventi una profondità di 1.27 cm.

Per quanto concerne la fessurazione, la legge di fatica considerata tiene conto degli effetti di **autoriparazione** del conglomerato bituminoso, derivanti dalle proprietà viscose del legante e dal maggior tempo di riposo tra l'applicazione di un carico ed il successivo che vi è nel caso reale rispetto alle più severe prove di laboratorio. Secondo l'Asphalt Institute tali effetti sono responsabili di una vita utile effettiva superiore di 18,4 volte rispetto a quella misurata dalle corrispondenti prove di laboratorio: ciò è tenuto in conto nella legge considerata poiché essa, una volta derivata dalla regressione dei dati di laboratorio, viene successivamente modificata applicando un fattore di traslazione S_{FC} pari a 18,4.

La verifica razionale delle pavimentazioni è stata effettuata utilizzando una schematizzazione di multi-strato elastico ed impiegando il codice di calcolo KENLAYER [8]. Il traffico è stato espresso in termini di ripetizioni di assi equivalenti singoli a ruote gemellate da 80 kN. La configurazione geometrica utilizzata prevede due impronte circolari di raggio 89,2 mm (a cui corrisponde una pressione di gonfiaggio di 800 kPa) distanziate trasversalmente di 0,315 metri.

Si è ipotizzato il raggiungimento di condizioni di perfetta aderenza tra gli strati legati a bitume e aderenza nulla tra questi e la fondazione. Condizioni di perfetta aderenza sono state ipotizzate anche tra fondazione e terreno di sottofondo.

2.6 RISULTATI DELLE VERIFICHE

Nella tabella seguente si riportano in sintesi i dati di input utilizzati per le verifiche.

Tipologia sovrastruttura		<i>Nuovo sedime A14 e tangenziale</i>	<i>Nuovo Svincolo Lazzaretto</i>	2A	2B	2C	2D
Traffico							
numero assi medio mensile	80 kN/mese	738'532	63'837	608'737	754'976	648'455	316'514

Spessori sovrastruttura							
H ₁ USURA	cm	4	4	4	4	4	4

Tabella 2-2. Riepilogo dati di input

Facendo riferimento ai criteri limite di progetto descritti in precedenza si è calcolato il danno cumulato corrispondente sia alla fessurazione a fatica sia alla formazione di ormaie utilizzando la legge espressa da Miner secondo la seguente relazione:

$$D = \sum_{i=1}^I \frac{n_i}{N_i}$$

dove:

- n_i è il numero effettivo di ripetizioni di assi transitati;
- N_i è il numero di ripetizioni di assi che portano a rottura il materiale, per le diverse condizioni di temperatura considerate.

I risultati delle verifiche strutturali sono riportate integralmente nell'**Allegato D**.

Nella tabella seguente è riportata una sintesi dei risultati espressi sotto forma di:

- **danno elementare** relativo ad ogni mese dell'anno medio;
- **danno cumulativo** relativo all'anno medio, ottenuto come somma algebrica dei danni elementari sopra detti;
- **vita utile**, corrispondente al numero di anni necessari al raggiungimento di un valore unitario del danno.

Tabella 2-3. Risultati della verifica strutturale

Sulla base dei calcoli effettuati le sovrastrutture di progetto risultano verificate in quanto la vita utile di calcolo risulta superiore alla vita di progetto di 20 anni.
