### Definizione

Per pendio s'intende una porzione di versante naturale il cui profilo originario è stato modificato da interventi artificiali rilevanti rispetto alla stabilità. Per frana s'intende una situazione di instabilità che interessa versanti naturali e coinvolgono volumi considerevoli di terreno.

### Introduzione all'analisi di stabilità

La risoluzione di un problema di stabilità richiede la presa in conto delle equazioni di campo e dei legami costitutivi. Le prime sono di equilibrio, le seconde descrivono il comportamento del terreno. Tali equazioni risultano particolarmente complesse in quanto i terreni sono dei sistemi multifase, che possono essere ricondotti a sistemi monofase solo in condizioni di terreno secco, o di analisi in condizioni drenate.

Nella maggior parte dei casi ci si trova a dover trattare un materiale che se saturo è per lo meno bifase, ciò rende la trattazione delle equazioni di equilibrio notevolmente complicata. Inoltre è praticamente impossibile definire una legge costitutiva di validità generale, in quanto i terreni presentano un comportamento non-lineare già a piccole deformazioni, sono anisotropi ed inoltre il loro comportamento dipende non solo dallo sforzo deviatorico ma anche da quello normale. A causa delle suddette difficoltà vengono introdotte delle ipotesi semplificative:

1. Si usano leggi costitutive semplificate: modello rigido perfettamente plastico. Si assume che la resistenza del materiale sia espressa unicamente dai parametri coesione ( $c$ ) e angolo di resistenza al taglio ( $\phi$ ), costanti per il terreno e caratteristici dello stato plastico; quindi si suppone valido il criterio di rottura di Mohr-Coulomb.
2. In alcuni casi vengono soddisfatte solo in parte le equazioni di equilibrio.

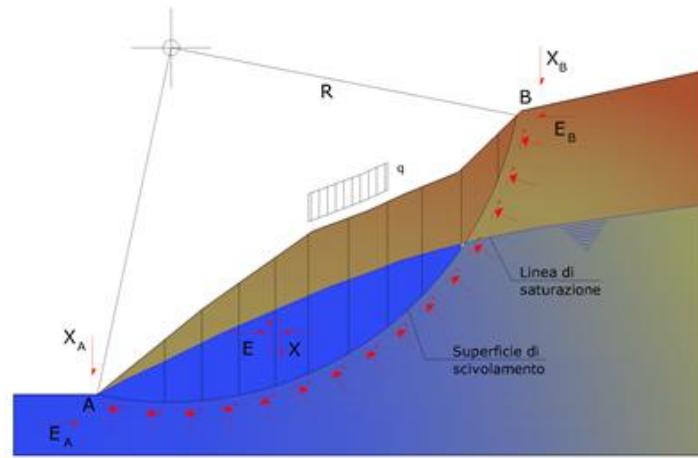

### Metodo equilibrio limite (LEM)

Il metodo dell'equilibrio limite consiste nello studiare l'equilibrio di un corpo rigido, costituito dal pendio e da una superficie di scorrimento di forma qualsiasi (linea retta, arco di cerchio, spirale logaritmica); da tale equilibrio vengono calcolate le tensioni da taglio ( $t$ ) e confrontate con la resistenza disponibile ( $t_f$ ), valutata secondo il criterio di rottura di Coulomb, da tale confronto ne scaturisce la prima indicazione sulla stabilità attraverso il coefficiente di sicurezza:

$$F = t_f / t$$

Tra i metodi dell'equilibrio limite alcuni considerano l'equilibrio globale del corpo rigido (Culman), altri a causa della non omogeneità dividono il corpo in conci considerando l'equilibrio di ciascuno (Fellenius, Bishop, Janbu ecc.).

Di seguito vengono discussi i metodi dell'equilibrio limite dei conci.

### Metodo dei conci

La massa interessata dallo scivolamento viene suddivisa in un numero conveniente di conci. Se il numero dei conci è pari a  $n$ , il problema presenta le seguenti incognite:

- $n$  valori delle forze normali  $N_i$  agenti sulla base di ciascun concio;
- $n$  valori delle forze di taglio alla base del concio  $T_i$ ;
- $(n-1)$  forze normali  $E_i$  agenti sull'interfaccia dei conci;
- $(n-1)$  forze tangenziali  $X_i$  agenti sull'interfaccia dei conci;
- $n$  valori della coordinata  $a$  che individua il punto di applicazione delle  $E_i$ ;
- $(n-1)$  valori della coordinata che individua il punto di applicazione delle  $X_i$ ;
- una incognita costituita dal fattore di sicurezza  $F$ .

Complessivamente le incognite sono  $(6n-2)$ .

Mentre le equazioni a disposizione sono:

- equazioni di equilibrio dei momenti  $n$ ;
- equazioni di equilibrio alla traslazione verticale  $n$ ;
- equazioni di equilibrio alla traslazione orizzontale  $n$ ;

- equazioni relative al criterio di rottura n.

Totale numero di equazioni 4n.

Il problema è staticamente indeterminato ed il grado di indeterminazione è pari a :

$$i = (6n - 2) - (4n) = 2n - 2$$

Il grado di indeterminazione si riduce ulteriormente a (n-2) in quanto si fa l'assunzione che  $N_i$  sia applicato nel punto medio della striscia. Ciò equivale ad ipotizzare che le tensioni normali totali siano uniformemente distribuite.

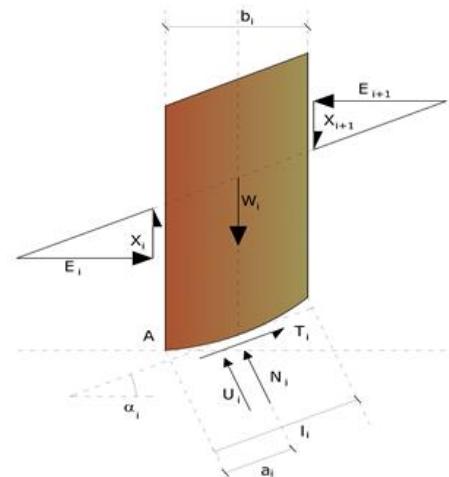

I diversi metodi che si basano sulla teoria dell'equilibrio limite si differenziano per il modo in cui vengono eliminate le (n-2) indeterminazioni.

## Metodo di Bishop (1955)

Con tale metodo non viene trascurato nessun contributo di forze agenti sui blocchi e fu il primo a descrivere i problemi legati ai metodi convenzionali. Le equazioni usate per risolvere il problema sono:

$$\sum F_y = 0, \quad \sum M_0 = 0 \quad \text{Criterio di rottura}$$

$$F = \frac{\sum \{ c_i \times b_i + (W_i - u_i \times b_i + \Delta X_i) \times \tan \varphi_i \} \times \frac{\sec \alpha_i}{1 + \tan \alpha_i \times \tan \varphi_i / F}}{\sum W_i \times \sin \alpha_i}$$

I valori di F e di DX per ogni elemento che soddisfano questa equazione danno una soluzione rigorosa al problema. Come prima approssimazione conviene porre DX = 0 ed iterare per il calcolo del fattore di sicurezza, tale procedimento è noto come metodo di Bishop ordinario, gli errori commessi rispetto al metodo completo sono di circa 1 %.
